Statement of Interest: A Tool For Mapping Concepts Between Two Ontologies

This statement of interest describes our ongoing work on tools for ontology mapping between two classification hierarchies. Our approach combines the recently emerging semantic markup language DAML+OIL (for ontology specification), the text-based classification technology (for similarity information collection), and Bayesian reasoning (for resolving uncertainty in similarity comparisons). This system will be used as part of the ITTALKS [1] system to allow multiple topic ontologies to be used to describe the subjects of talks and the interests of users. The ontology maps generated by our tools can be used to recognize that a talk described by terms in one ontology might be of interest to a user who has described her interests using terms drawn from another. A more complete description of this work is available at [2].

Ontologies: The two hierarchies we used as examples are ACM topic ontology and a small ITTALKS topic ontology that organizes classes of IT related talks in a way different from ACM classification. Both ontologies, as well as the output mappings, are marked up in DAML+OIL. Each concept/class in an ontology is associated with a set of exemplars, which are URLs to the locations of text documents thought to belong to that class.

Text-based classification: The Rainbow text classifier [3] is used to generate similarity scores between concepts in the two ontologies based on their associated exemplar documents. First, a model is built for each ontology, which primarily contains statistical information about the exemplars associated with each concept in that ontology. Then, the similarity score $S_s(A_i, B_j)$ from concept $B_j$ in ontology $B$ to concept $A_i$ in ontology $A$ can be obtained by comparing the exemplars of $B_j$ against the model of ontology $A$. In essence, $S_s(A_i, B_j)$ measures similarity between exemplars associated with $B_j$ and those with $A_i$.

Bayesian subsumption: $B_j$ may (partially) match more than one concept in $A$, each with a different similarity score. Also since a non-leaf node is a superclass of its children, its exemplars should include both those associated with it and those with all of its descendants in the hierarchy. Therefore, non-leaf nodes need to synthesize scores from their descendants before the final mapping can be selected. This is accomplished by a Bayesian extension of the subsumption operation of description logics. In this approach, we assume that all leaves in a hierarchy form a mutually exclusive and exhaustive set, and take the score $S_s(A_i, B_j)$ as $P(A_i \mid B_j)$ if $B_j$ is a leaf. (If $B_j$ is a non-leaf,

$$P(A_i \mid B_j) = \sum_{B_k \in B_j} P(A_i \mid B_k) \cdots P(B_k)/P(B_j)$$

can be computed from the scores $S_s(A_k, B_j)$ if $P(B_k)/P(B_j)$ are available.)

Then, the concept $A^*$ is said to be the best mapping of a concept $B_j$ if (1) $P(A^* \mid B_j) > 0.5$, and (2) none of $A^*$'s children $A_k$ has $P(A_k \mid B_j) > 0.5$. These two conditions together give $A^*$ the flavor of the most specific subsumption in description logics.

The algorithm of finding $A^*$ is a simple procedure that takes two passes over the hierarchy of $A$:

- **Bottom-up**: Synthesize the probability for each non-leaf node $A_i$ as $P(A_i \mid B_j) = \sum_{A_k \in \text{child}(A_i)} P(A_k \mid B_j)$.
- **Top-down**: Recursively search for $A^*$, starting from $A_{\text{root}}$. If it does not satisfy the two conditions, then move down to its most probable child.

Experiment results: Preliminary experiments have been conducted over the two topic ontologies for a set of selected concepts. The resulting mappings were ranked by their respective probabilities, and were given to five people knowledgeable about computer science for evaluation. For the top 5%, 10%, 15%, and 20% ranked mappings, acceptable rates (a mapping is acceptable if 4 of the 5 evaluators agreed) were 0.8, 0.7, 0.68, 0.65, respectively.

Encouraged by these results, we plan to continue this work along several directions, including replacing the mutual exclusive assumption with more realistic models of inter-class dependencies based on Bayesian networks, utilizing properties associated with individual classes, and conducting additional experiments of larger scales.
